## ACKNOWLEDGMENTS

## MANY THANKS TO THE FOLLOWING

## INDIVIDUALS AND ORGANIZATIONS:

Jo-Ann Taylor designed the project with the assistance of William Wilcox, and served as principal investigator, author, and MVC project quality assurance officer. Shawn McCormack assembled the land use database. William Wilcox provided on-the-spot support throughout the project. Irene Fyler performed bookkeeping duties.

This project has been financed partially with Federal Funds from the Environmental Protection Agency (EPA) to the Massachusetts Department of Environmental Protection (the Department) under a s. 604(b) Water Quality Management Planning Grant (\# 99-02/604). The contents do not necessarily reflect the views and policies of EPA or the Department, nor does the mention of trade names or commercial products constitute endorsement or recommendation for use. Pamela Truesdale was very helpful as project officer for the Department. The Islands Watershed Team, particularly Patti Kellogg, provided considerable commentary and hosted a public session.

## EXECUTIVE SUMMARY

Lagoon Pond is a 538 acre coastal pond situated on the north shore of Martha's Vineyard, shared by the Towns of Tisbury and Oak Bluffs. It is permanently opened to Vineyard Haven Harbor by means of a drawbridge. The pond supports commercially important shellfish resources, as well as diverse fish populations, including herring which are an important food source for both commercial offshore fish species and nearshore recreational fish species such as bluefish and striped bass. In recent years, the pond has shown symptoms of stress which may reflect increased human activity in the watershed. There has been extensive residential growth in the watershed. The issue of nitrogen loading is a key to developing an appropriate response to issues including the nature of future growth in the watershed of each pond. The unknowns under investigation included: the quality of the groundwater discharging into each pond and where the discharge is occurring; the projected nitrogen loads based on buildout including various scenarios, and what effect they will have; the steps that should be taken by the towns to assure that the water quality in the pond is maintained.

The entire watershed for the pond covers 4,406.2 acres, including 538 acres for the pond itself. The present nitrogen load to the watershed is approximately $\mathbf{1 7 , 2 4 0}$ kilograms per year, from the following sources:

Kilograms/year

| Rain, runoff | $\mathbf{6 , 4 1 3}$ |
| :--- | ---: |
| Septic Systems |  |
| Residential | $\mathbf{7 , 5 9 7}$ |
| Commercial, municipal | 1,436 |
| Farms | 1,062 |
| Lawns | $\mathbf{7 3 2}$ |
| Total | $\mathbf{1 7 , 2 4 0}$ |

Land use investigations revealed 34 commercial units on 16.35 acres of commercial land and 1,724 houses and guesthouses on $1,377.54$ acres of residential land, of which 349.36 acres have potential for further subdivision. Of 1,541.81 acres of vacant land, protected open space accounts for 654.82 acres. Of the remainder, 370.38 acres of land is potentially available for further subdivision, and the remaining 516.61 acres of vacant land is without further subdivision potential. Farms occupy the remaining 111.74 acres in the watershed.

MVC developed a recommended nitrogen loading limit of 17,000 kilograms per year for the entire watershed, and compared the limit with the existing and projected nitrogen loads:

Kilograms/year

Current Nitrogen Load
Nitrogen Load at Low Growth
Nitrogen Load at Moderate Growth
Nitrogen Load at High Growth

17,240
20,668
22,439
26,806

The conclusion from the calculations is that the proposed limit is quite close to the present load. Water quality sampling data also support that conclusion.

MVC developed nitrogen management recommendations for the watershed as follows:

1. ADOPT 17,000 KILOGRAMS AS AN ANNUAL LOAD LIMIT FOR THE WATERSHED.

## SEPTIC SYSTEMS

- Determine growth needs and desires for the watershed area in both towns.
- Encourage advanced nitrogen removal for new septic systems and consider possible extension of Tisbury municipal sewer service area.
- Revise zoning and board of health regulations to support the $17,000 \mathrm{~kg}$ limit. Consider a watershed-wide DCPC to develop and implement those regulations.
- Maximize acquisition or protection of much of the remaining open space in the watershed. Particularly consider the 370.38 acres with further subdivision potential.

RAINFALL AND RUNOFF

- Construct and maintain structural solutions where needed to remediate existing problems, particularly in the vicinity of Mud Creek in Tisbury and the specific sites at Hudson Avenue, Lagoon Road and Vineyard Avenue Extension in Oak Bluffs. Review town regulations regarding proper drainage design in future projects; Tisbury might want to adopt stormwater regulations similar to those adopted by the Oak Bluffs Board of Health.

## LAWNS AND LANDSCAPING

- Educate homeowners and professional landscapers about using native plants and about fertilizer impacts.

AGRICULTURE

- Encourage low-nitrogen farm activities where practical, such as in conjunction with open space ventures. Examples are legumes such as clover, alfalfa and beans, and grass seed mixture for hay and pasture.

## SHELLFISH AND HERRING

- Promote shellfish as nutrient consumers, along with herring. Ensure that their habitats are protected.

2. FURTHER ASSESSMENT AND MONITORING

- Continue water sampling, particularly focusing on the "tributaries" of Mud Creek and Brush Pond. Include some continuous recorded logs of dissolved oxygen over several daily cycles together.
- Perform updates to the eelgrass inventory, at five year intervals. Watch for changes in the algae and weed population.
- Continue to investigate the complexities of circulation in the pond. Ensure that the flushing formulas used to calculate the nitrogen loading limit are appropriate for the realities of circulation in this unusually long, narrow and deep water body. Investigate stratification in the deeper areas.

## WATER QUALITY MEASUREMENTS

When looking at water quality in terms of load and limits, it is important to look at the existing water quality conditions. Water sampling results provide numerical data, and habitat conditions are evident by observations of the health of nutrient-sensitive species like eelgrass.

## NUTRIENT CYCLE

Nitrogen and phosphorous are the "building blocks" of plant material. Phosphate particles are filtered out over distance and remain adsorbed to soil particles. Nitrate, on the other hand, is extremely soluble and stable and will travel great distances in groundwater to be discharged to the pond. Nitrogen enters the ground as organic nitrogen, ammonium $\left(\mathrm{NH}_{4}{ }^{+}\right)$or nitrate $\left(\mathrm{NO}_{3}{ }^{-}\right)$from wastes or fertilizers. Most nitrogen that is introduced to aerobic subaqueous environments, such as the central aquifer of Martha's Vineyard, is converted to nitrate. In the soil, in the layer between the ground surface and the water table, organic nitrogen is converted to ammonium $\left(\mathrm{NH}_{4}{ }^{+}\right)$and ammonium to nitrate $\left(\mathrm{NO}_{3}{ }^{-}\right)$, the stable form of nitrogen in groundwater. In addition to being the stable form of nitrogen for traveling in the groundwater, nitrate is, along with ammonium, a form of nitrogen which is readily taken up and used by plants. There is a process known as denitrification which reduces nitrate $\left(\mathrm{NO}_{3}{ }^{-}\right)$to $\mathrm{N}_{2} \mathrm{O}$ and $\mathrm{N}_{2}$, forms of nitrogen which are not readily usable by plants. However, this process only occurs in a reducing environment such as peat. Most of the nitrate in the groundwater will reach the pond and become available for plant growth. The reducing environment may be recreated in a peat bed, recirculating sand filter or Bioclere system, which may be constructed as part of a septic system.

Nutrients in excess may stimulate excessive undesirable plant growth. Such plant growth may occur in the form of rooted plants and/or algae, at the expense of growth of more desirable forms of plant life such as eelgrass. The health of the eelgrass beds depends on the availability of sunlight for photosynthesis. In nutrient-rich waters, certain forms of epiphytic algae may attach themselves to the individual blades of eelgrass, effectively cutting off the supply of sunlight and reducing growth and overall health. In poor condition, the eelgrass is then less resistant to disease. Some algae blooms, such as red tide, may be quite destructive in terms of immediate consequences. Fish kills may occur when too much of the oxygen in the water is used by the bacteria which decompose dead plant matter. Decaying algae and seaweed may create localized odor problems. A more insidious effect of nutrient enrichment is the long
term filling in of the pond with organic matter, which process is known as eutrophication. Loading the pond with organic matter would have the long term effect of changing the bottom from sand and gravel to organic mud. The sand and gravel bottom is preferred shellfish habitat as well as spawning and nursery habitat for a number of fish species including the commercially important winter flounder.

The nutrient which is typically the limiting factor for plant growth in fresh water is phosphorous. The typical nutrient limiting growth in salt ponds is nitrogen. The ratio of total nitrogen/total phosphorous determines whether growth is limited by nitrogen (TN/TP < 15/1) or by phosphorous (TN/TP > 15/1). According to the draft Island Coastal Ponds Water Quality Study ${ }^{1}$, most of Lagoon Pond is nitrogen limited, except for the fresh waters of Mud Creek and Upper Lagoon Pond.

## EELGRASS AND ALGAE

There is some evidence that eelgrass in Lagoon Pond is in a state of decline. Massachusetts' Department of Environmental Protection performed mapping of the aerial extent of the eelgrass beds in 1994 and updated the maps in 2000. The maps reveal less extensive eelgrass coverage in 2000. There is a particularly striking loss evident from the tip of Hines Point to Lagoon Avenue, on the Tisbury side of the main body of the pond. Extensive beds there in 1994 were greatly reduced in lateral extent in 2000, almost to the point of disappearance. In 1999, Phil Colarusso, of the U.S. Environmental Protection Agency, performed a different type of analysis, looking at the condition of the eelgrass crop, as well as overall distribution. His preliminary conclusions are that eelgrass in Lagoon Pond is in a rapid state of decline.

According to the Island Coastal Ponds Water Quality Study ${ }^{2}$, the Upper Pond produced a significant algae bloom in late August and September, 1995, when particulate carbon and nitrogen exceeded the rest of the Pond by 5 to 8 times, and the chlorophyll A levels were about 15 times the rest of the sampling sites in the Pond. Oak Bluffs Shellfish Constable David Grunden ${ }^{3}$ reported evidence of a dinoflagellate Prorocentrum, that is known to be hazardous to shellfish. M.V. Shellfish Group Director Rick Karney ${ }^{4}$ has reported repeated problems at the shellfish hatchery with dinoflagellate blooms, particularly around Labor Day.

[^0]
## WATER QUALITY SAMPLING RESULTS

In the U.S.G.S. hydrology study, Delaney reported Island-wide nitrate concentrations: "Nitrate-nitrogen concentration, nitrate reported as nitrogen, is generally low (median concentration $0.6 \mathrm{mg} / \mathrm{L}$ - maximum concentration less than $6 \mathrm{mg} / \mathrm{L}$ ) at 48 sampling sites throughout the Island."5. The Diagnostic/Feasibility Study for Lagoon Pond oak Bluffs/Tisbury ${ }^{6}$ reported elevated nitrogen levels of 4 to $10 \mathrm{mg} / \mathrm{l}$ in shallow groundwater wells in areas associated with dense housing, peaking in spring and late summer. Nutrients were also associated with runoff. The Mud Creek and Brush Pond tributaries contributed peak loading in response to rain events, over the first one to two hours of a summer rain storm. Upper Lagoon Pond contributed elevated nitrogen levels ( 1.0 to $2.5 \mathrm{mg} / \mathrm{l}$ ), with nutrient washout 3 to 4 hours after the start of a summer rainstorm. According to the Island Coastal Ponds Water Quality Study, Mud Creek, Brush Pond and Upper Lagoon Pond remained sources of elevated nutrient levels in 1995 and 1996. Nutrient levels at Mud Creek, Brush Pond and Upper Lagoon Pond were considerably higher than those of most of the other Island samples, and in some instances even exceeded levels measured in Buzzards Bay. Compare, for instance, the levels of Dissolved Inorganic Nitrogen found at Brush Pond, Mud Creek and Upper Lagoon Pond to those in the Outer Harbor:

|  | SOLVE | ORGANI | TROGEN | /L) |
| :---: | :---: | :---: | :---: | :---: |
|  | Brush Pond | Mud Creek | Upper <br> L. Pond | Outer Harbor |
| Max | 5.12 | 68.21 | 14.22 | 1.96 |
| Min | . 22 | 1.4 | . 3 | . 3 |
| Average | 2.36 | 17.00 | 3.32 | . 98 |

In general, the "tributaries" had elevated levels of ammonium and nitrate when compared to the "in-pond" stations. This was the case during the sampling rounds in spring and late summer/early fall sampling rounds at the Upper Pond. Mud Creek was considerably elevated above the rest of the Pond for these two parameters throughout the study. Brush Pond had elevated levels at various times throughout the course of the study.

[^1]
## WATERSHED DELINEATION \& RECHARGE ESTIMATES

## WATERSHED DELINEATION

The Lagoon Pond watershed was delineated based on a number of available sources of groundwater contours. In 1980, Delaney mapped groundwater contours that illustrate the general recharge area for the pond ${ }^{7}$. In 1984, the Martha's Vineyard Commission ${ }^{8}$ used the Delaney contours to estimate a recharge area of approximately 4470 acres. In his 1986 report ${ }^{9}$, Arthur Gaines estimated the watershed area to be 13.5-19.7 square kilometers (3336-4868 acres), with the suggestion that the larger estimate may be more in keeping with observed discharge. The larger estimate corresponds with the 1984 MVC estimate as based on the Delaney contours. The smaller estimate corresponds with groundwater contours mapped by clifford Kaye, as shown in the MVC's 1977 draft Water Quality Management Plan. Bruce Poole ${ }^{10}$ reported an estimate of 4868 acres, using the high end of the Gaines/Delaney estimate.

MVC used the existing references as a basis for the overall delineation, then used new information to refine the boundaries, where available. More recent groundwater contours have been made available in conjunction with the new Zone II delineations and with planning for the Town of Tisbury's proposed sewer system. The sewer planning study ${ }^{11}$ provided detail in the area of downtown Tisbury. The groundwater contours in the Zone II delineation ${ }^{12}$ provide detail in the densely developed part of the Oak Bluffs side. The two new references provide helpful detail in the most densely developed areas, where the detail is most useful. The "tail" of the watershed is not as distinctive, but covers territory, such as the State Forest, that is unlikely to be developed.

MVC used the above references to plot the watershed as shown on the attachment. MVC then measured the watershed with a planimeter, at 4,367.4 acres. MVC checked the watershed measurement by GIS scanned calculation of 4,445.02 acres. MVC averaged the two and arrived at a final figure of $4,406.2$ acres, including 538 acres for the pond itself, a figure that is consistent with earlier delineations.

[^2]
"Approximate demarkation of the groundwater recharge area for Lagoon Pond. The smaller area corresponds more closely with the analysis of Kaye (in MVC. 1977) while the larger area more nearly follows Delaney

Dis charge calculations for Lagoon Pond suggest the larger area may be more appropriate.

Taken from Gaines, Arthur, Jr., W.H.O.I., 1986, Lagoon Pond Study: An Assessment of Environmental Issues and Observations on the Estuarine System

Taken from Stone Environmental, Inc., 1999

## ANNUAL RECHARGE ESTIMATES

The average annual precipitation as recorded in Edgartown was 45.82 inches from 1945 to 1975 (New England Climatic Service-Climatological Summary). A portion of this rainfall reaches the water table and flows toward the pond. The remainder is lost to evaporation or is taken up by vegetation. The portion reaching the groundwater is not precisely known, but estimates have been made for various locations around Cape Cod and Martha's Vineyard, as shown below:

| ANNUAL RECHARGE IN INCHES |  |  |
| :---: | :---: | :---: |
| Source | Location | Recharge |
| USGS, 1980 | Martha's Vineyard | 22.2 |
| Leblanc et al, 1986 | Cape Cod West | 22.2 |
| Eichner et al, 1992 | Falmouth, Bourne | 21 |
| Leblanc, 1982 | Otis Air Force Base | 21 |
| Eichner et al, 1992 | Sandwich, Mashpee | 19 |
| Eichner et al, 1992 | Barnstable, Dennis \& Yarmouth | 18 |
| Leblanc et al, 1986 | Cape Cod East | 18 |
| Delaney et al, 1972 | Truro | 18.3 |
| Eichner et al, 1992 | Brewster, Harwich | 17 |
| Eichner et al, 1992 | Chatham, Orleans, Eastham, Wellfleet, Truro \& Provincetown | 16 |

MVC used a recharge estimate of 22.2 inches, from the USGS source for Martha's Vineyard. The estimate is also consistent with the estimates for western Cape Cod. Using the recharge estimate of 22.2 inches, MVC calculated the recharge for the 4406.2 acre Lagoon Pond watershed (3,868.2 acres without the 538 acre pond area) to be 8.8 million cubic meters, or 2.33 billion gallons $(6.38$ million gallons per day).

In addition to the groundwater recharge, the 538 acre pond surface receives rainfall in the amount of 45.82 inches per year. Annual rainfall totals 2.5 million cubic meters, or 669.3 million gallons, or 1.8 million gallons per day.

## NITROGEN LOADING TO THE WATEREHED

Pond water quality is greatly influenced by human use and development of the surrounding lands. In Banks' History of Martha's Vineyard Dukes County Massachusetts ${ }^{13}$, there is much information about land use in the Lagoon Pond area by the Indians and by the early white settlers. Appended to this document is a section which contains many interesting passages from Banks' history, including identification of many place names. Regarding the first recorded residents, Banks wrote about the early settlements, including one at the head of the pond:
"It is probable that smaller communities made abiding-places within the limits of the territorial authority of each petty sachem. In this way, $I$ believe, we may infer that Wekwetuckauke (the lagoon), Sanchacantacket, Onkokemmaug (North Tisbury) and Nashowakemmuck (Chilmark) were the locations of such subordinate villages. Of the character of these settlements it can be said that they had no permanency. Composed as they were of loosely constructed wigwams, they were easily transported from place to place, as the requirements of the season demanded. In the summer they were doubtless picketed about the inlets of the coast, while in winter they were removed to the protection of the woods and hills from the icy blasts of the north. The circumscribed territory, however, prevented extended migration, and within a small compass the various companies owning fealty to the local great men, moved from place to place, when the refuse heaps became too large or the game grew too wary. Their dwellings were known as wigwams, a corruption of the Algonquian word 'wekowomut', meaning in our language, a house. The younger Mayhew described these structures as 'made with small poles like an arbor covered with mats, and their fire is in the midst, over which they leave a place for the smoak to go out at'. This was in 1650, and probably is a correct description of them as they were used before the coming of the whites. The Island Indians did not use skins for a covering like those on the mainland, as there were not any animals numerous enough to supply them for that purpose. The mats were woven from the common marsh flag, or flower-de-luce, and probably long, native grasses were added for binding."

Banks wrote about the pastoral setting of the interior woodlands at that time: "...while westward on the shores of the Lagoon were the dingy wigwams of the remnants of the Indian race. Over

[^3]all this section great groves of tall pine and spreading oaks furnished welcome shade to the herds of cattle that browsed in the 'Great Pasture' on the borders of Squash meadow, and the only sounds that echoed through these woods were the calls of lowing kine, the bleating of a stray sheep, and the occasional crack of $a$ woodsman's axe. This condition lasted for a generation in the first third of the nineteenth century, before its primeval stillness was invaded by a throng of people who were destined to turn it into a 'city' of paved streets and electric lights.".

## RESIDENTIAL LAND USE AND PROJECTIONS

MVC identified individual lots in the watershed as built or unbuilt (MVC buildout database, 1999) and constructed spreadsheets identifying individual lots in each of the three towns. Those spreadsheets are appended to this document. Land use investigations revealed 1,724 houses and guesthouses in the watershed. In addition to estimating the present number of houses in the watershed, it is important to project the number of dwellings at buildout, when all of the available land is ultimately developed or protected or open space. In order to project buildout scenarios, it is necessary to understand the growth controls in place. On the Oak Bluffs side, most of the watershed is located in the R-3 zoning district (60,000 $\mathrm{ft}^{2}$ minimum lot size). Some land in the northern part is in the $R-1$ district ( 10,000 $f t^{2}$ ), and some land in the southern part is in the R4 District (120,000 $\mathrm{ft}^{2}$ minimum lot size). The diminutive Health Care District is also located within the watershed. On the Tisbury side of the main body of the pond, waterfront lands are evenly divided between $R-20$ ( $20,000 \mathrm{ft}^{2}$ minimum lot size) and $R-50\left(50,000 \mathrm{ft}^{2}\right)$ zoning districts. Land use on the West Arm is residential ( $\mathrm{R}-50$ ) on the Hines Point side and commercial (Waterfront District) on the other. The Town-owned Lagoon Harbor Park is regulated by its own Lagoon Harbor Park District. Growth controls are presented in table form on the following page.

## BUILDOUT PROJECTIONS

MVC reviewed existing controls as summarized in the previous table, and developed three different buildout scenarios. The concept of buildout implies that all available land is used for something, whether it is used as a houselot, farmland, protected open space or commercial use. It may be that ultimate buildout never happens, but speculation is possible and should be based on growth controls in place. In the high growth scenario, new lots would be 3 acres in West Tisbury and in Oak Bluffs' R4 District, with about $5 \%$ subtracted for roads. Other projected subdivisions would be: 1.5 acres in Oak Bluffs' R3 District, . 5 acre in Tisbury's R20 and just over one quarter acre (.31) in Tisbury's R10 and Oak Bluffs' R1 Districts. Roads are included in all numbers. When lots fall within either the Lagoon Pond DCPC or a Zone 2, subdivision was limited in the projections as it would be by those restrictions. Roads are included in all calculations.

Under a moderate growth scenario, new subdivisions would have lots that are 4.5 acres in West Tisbury and in Oak Bluffs' R4 District, 2 acres in Oak Bluffs' R3, one acre in Tisbury's R20, .5 acre in Oak Bluffs' R1 and in Tisbury's R10.

Under a low growth scenario, new lots would be six acres in West Tisbury and in Oak Bluffs' R4 District, with about 5\% subtracted for roads, 3 acres in Oak Bluffs' R3 District, 1.5 acres in Tisbury's R20, and . 75 acre in Tisbury's R10 and in Oak Bluffs' R1.

The 1,724 houses and guesthouses in the watershed are sited on 1,377.54 acres of residential land, of which 349.36 acres have potential for further subdivision. Of 1,541.81 acres of vacant land, protected open space accounts for 654.82 acres. Of the remainder, 370.38 acres of land is potentially available for further subdivision, and the remaining 516.61 acres of vacant land is without further subdivision potential. Farms occupy the remaining 111.74 acres in the watershed.

The pie chart that follows is meant to graphically display the land use and projections:

| Land Use | Acres |
| ---: | ---: |
| built, subdividable | 349.36 |
| vacant, subdividable | 370.38 |
| vacant | 516.61 |

## Moderate Growth

(3.7\%)

## LOAD ESTIMATES

Next, MVC assigned nitrogen load estimates to the current land use and to the projections. MVC used statistical averages to calculate persons per year-round household and ratio of seasonal to year-round dwellings (MISER - Mass. Institute for Social and Economic Research). In Oak Bluffs, 2.26 persons reside in each year-round dwelling, and $49 \%$ of dwellings are seasonally occupied. The recent Oak Bluffs Master Plan Survey found an average of 4.77 persons per seasonal dwelling (Oak Bluffs Master Plan, 1998), and that figure was used to estimate numbers of seasonal persons throughout the watershed. It is assumed that each year-round dwelling is occupied by guests for 25 days. Seasonal dwellings are assumed to be occupied by 4.77 persons for 75 days and by the year-round number for an additional 30 days of shoulder seasons. In Tisbury, each year-round dwelling is occupied by 2.33 persons, and $30 \%$ of dwellings are seasonally occupied. In West Tisbury, 2.87 persons occupy each year-round dwelling, and 29\% of dwellings are seasonally occupied.

Numbers of guesthouses were estimated from the controls in place. Oak Bluffs allows "accessory dwellings" provided there are 7500 square feet of vacant land on the lot. Board of Health regulations for the Lagoon Pond DCPC and the Zone 2's effectively reduce the number of potential guesthouses by about half. Tisbury allows "guesthouses" on lots that are larger than the minimum lot size by 25\%. Lagoon Pond DCPC regulations reduce the numbers. West Tisbury allows "subordinate dwellings" on lots of three acres or more. There are only 11 lots of 3 acres or more in the West Tisbury portion of the watershed. Guesthouses were presumed to house the same number of persons as the principal dwelling.

MVC calculated the septic load based on $35 \mathrm{mg} / \mathrm{l}$ nitrogen and 48 gal/person/day, as was used for the Edgartown Great Pond watershed ${ }^{14}$, as follows:
septic sitiems
$35 \mathrm{mg} / \mathrm{N}$ in sewage $X 48$ gallons/person/fay $=.0062 \mathrm{~kg} / \mathrm{personfjear}$ Nitrogen
Oak Buffs $\quad 1053$ dwellings +53 guesthouses ( $518+26$ seasonal: 4.77 persons/house $\times 75$ days +2.26 persons/house $\times 30$ days)
544 houses X 425.55 persons/year X. $00622=1440 \mathrm{~kg}$
( $535+27$ year-round: 2.26 persons/house $\times 365$ days +2.26 persons/house $\times 25$ days)
562 houses X 881.4 persons/year $\mathrm{X} .00622=3081 \mathrm{~kg}$
Tisbury $\quad 445$ dwellings +31 guesthouses ( $135+9$ seasonal: 4.77 persons/house $\times 75$ days +2.33 persons/house $X 30$ days)
144 houses X 427.65 persons/year X. $00622=383 \mathrm{~kg}$
( $310+22$ year-round: 2.33 persons/house $\times 365$ days +2.33 persons/house $\times 25$ days)
332 houses $X 908.7$ persons/year $X .00622=1877 \mathrm{~kg}$
West Tisbury $\quad 142$ dwellings +18 guesthouses ( 41 seasonal: 4.77 persons/house X 75 days +2.87 persons/house X 30 days)
41 houses X 443.85 persons/year X. $00622=113 \mathrm{~kg}$
(101 year-round: 2.87 persons/house $\times 365$ days +2.87 persons/house $\times 25$ days)
101 houses X 1119.3 persons/year X . $00622=703 \mathrm{~kg}$
total septic systems:
$4521+2260+816=7597 \mathrm{~kg}$ Nyear

[^4]The projected loads were calculated in similar proportions, assuming the same occupancy rates and seasonality. The projected loads are as follows:

Load from Residential Septic Systems

| Existing | $7,597 \mathrm{~kg}$ |
| :--- | ---: |
| Low Growth | $10,738 \mathrm{~kg}$ |
| Moderate Growth | $11,876 \mathrm{~kg}$ |
| High Growth | $14,138 \mathrm{~kg}$ |

## RAIN AND RUNOFF

Rain and runoff contribute atmospheric nitrogen to the watershed. After extensive literature review and consideration of wet deposition data at Provincetown since 1981, the Boston University Marine Program ${ }^{15}$ uses a value of 15 kg per hectare for total nitrogen in rainfall. MVC calculated the load from rainfall directly on the pond to be $3,267 \mathrm{~kg}$ of total nitrogen, using the value 15 kg per hectare.

Rain also falls on the landward portion of the watershed. MVC has calculated this groundwater recharge to be 8.8 million gallons per year. When the total acreage of lots in the watershed is added, the lots add up to about $79 \%$ of the total acreage measured by planimeter. Because of the density of development, it is easy to believe that 21\% of the watershed area could be found in roadways that are not included in the acreage of lot. MVC divided the recharge at the rate of $79 \%$ background nitrogen levels and $21 \%$ runoff nitrogen levels. Assigning $21 \%$ of the watershed to runoff areas may be on the high side, but it is not unrealistic, considering that much of the watershed slopes fairly steeply towards the pond and that runoff discharge is known to contribute to the water quality "hot spots" in the pond, particularly at Mud Creek. MVC used values of $.05 \mathrm{mg} / \mathrm{l}$ and $1.5 \mathrm{mg} / \mathrm{l}$, respectively, for nitrate nitrogen in rainfall discharged through groundwater and rainfall discharged as runoff, as recommended by the Buzzards Bay Project ${ }^{16}$.

[^5]RAINRUNOFF
through groundw ater recharge:
$.05 \mathrm{mg} / 1 \times 6.9$ million $\mathrm{m} \wedge 3 \times 1000 \mathrm{l} / \mathrm{m}^{\wedge} 3 \times \mathrm{xg} / 1 \mathrm{million} \mathrm{mg}=345 \mathrm{~kg}$ through runoff:
$1.5 \mathrm{mg} / 1 \times 1.9 \mathrm{mill} . \mathrm{m}^{\wedge} 3 \times 1000 \mathrm{l} / \mathrm{m}^{\wedge} 3 \mathrm{X} \mathrm{kg} / 1 \mathrm{million} \mathrm{mg}=2801 \mathrm{~kg}$
through direct precipitation on pond surface: (pond surface $=538$ acres)
$15 \mathrm{~kg} /$ hectare X 538 acres X 1 hectare/ 2.47 acres $=3267.2 \mathrm{~kg}$
total rainfrunoff:
$345+2801+3267 \mathrm{~kg}$ Nyear $=6413 \mathrm{~kg}$ Nyear
A total of 6413 kg of atmospheric nitrogen per year is estimated to contribute to the watershed from rainfall in the form of rain, groundwater discharge and runoff. For planning purposes, the rain and runoff contribution is expected to remain constant through all growth scenarios.

## COMMERCIAL AND MUNICIPAL LOAD AND PROJECTIONS

Although the vast majority of the watershed is residentially zoned, there is a special commercial area on the Tisbury side. Tisbury's commercial Waterfront District is an integral part of the heart of Tisbury's working waterfront. This commercial part of the watershed stands in stark contrast to the remaining residential lands. The commercial waterfront retains the boat-building and maintenance industries which have occupied the waterfront since colonial days. of special planning interest are the large structures remaining from the days when much of the Island's building supplies were brought in bulk, landed and stored right on shore. The building trades are still represented in the large warehouse-sized structures, but pressures on these land-intensive uses have driven many to relocate to Tisbury's State Road business area. The fate of these large structures and associated vacant lands is a definite planning concern.

In addition to the individual commercial uses, there are a number of municipal and other large contributors. The Island's high school, skating rink and hospital are located within the watershed. The Town of Oak Bluffs used to operate septage lagoons for disposal of septage from on-lot systems. The lagoons are closed, but have input nutrients that will continue to influence the pond for approximately another 19 years. Two large elderly housing projects, Hillside Village and Woodside Village, are located within the watershed.

MVC calculated existing load at $35 \mathrm{mg} / \mathrm{l}, \mathrm{using}$ Title V figures for gallons per day for various uses, unless other data were available. The load from Martha's Vineyard Hospital is based on measured discharges from the hospital's treatment plant. Projections were based on increased intensity of use. For instance, the "warehouse" loads are the boatyards and building trades occupying very large
structures with little nitrogen contribution. In the low growth scenario, these lots remain at the same intensity of use, and are assigned the same flows. The vacant commercial lots are also assigned the "warehouse" flows for lowintensity uses. In the moderate growth scenario, these land intensive uses have been squeezed out of the waterfront and replaced by the next level of intensity, represented by "retail" flows. (The progression from "warehouse" to "retail" is intended to represent a change in intensity of use and increased sewage flows. There is no reason to believe that the boatyards would all become retail stores.) In the high growth scenario, the next level of intensity is represented by "office" flows. The projections for the lots that are now used at "office" level intensity include use as restaurants and mixed uses that would include some restaurant seats and some other high intensity uses.

The estimated load and projections are as follows:
Commercial/Municipal Load

| Present | $1,436 \mathrm{~kg}$ |
| :--- | :--- |
| Low Growth | $1,382 \mathrm{~kg}$ |
| Moderate Growth | $1,557 \mathrm{~kg}$ |
| High Growth | $2,948 \mathrm{~kg}$ |

Note that the Low Growth scenario projects a reduction in load. That reduction results from the recent closure of the Oak Bluffs septage lagoons, and from Tisbury's proposal to provide sewer service to a number of the commercial properties in the Waterfront District.

The table on the following pages details the commercial and municipal influences in the watershed, with load projections:

LAWNS
A certain amount of nitrogen leaches into the groundwater from residential application of lawn fertilizer. In order to assess the impacts of lawns, MVC performed a field survey of lawn sizes and intensity of fertilization, for each neighborhood in the watershed. Intensity of fertilization was determined by the appearance of the lawns, and lawn size was measured by tape measure and by pacing with a known stride. A leaching loss rate of $25 \%$ was used to calculate nitrogen input to the groundwater, as shown in the table on the following page. Existing load was estimated to be 732 kg per year.

For the buildout projections, various assumptions were made regarding lawn care and size. For the low growth scenario, average lawn fertilizer application rate increases to 1.5 lb per 1000 square foot per year (from the present average of 1.42 lb ), lawn size proportions remain constant, and the number of households that maintain a lawn remains steady at $60 \%$. For the moderate growth scenario, lawn size proportions remain the same, fertilizer application rates increases to 1.5 lb per 1000 square feet per year, and 65\% of households maintain lawns. For the high growth scenario, fertilizer application rates increase to 2.2 lb per 1000 square feet per year, lawn size proportions remain constant and $65 \%$ of households maintain lawns.

Farms occupy 111.74 acres in the watershed. Each farm in the watershed was identified by use and acreage. Each use was assigned a rate of fertilization and a leaching loss rate. The total contribution from agricultural uses was estimated at 1062 kilograms per year. Agricultural use and nitrogen contribution were assumed to remain constant for all growth scenarios.

## FLUSHING CHARACTERISTICS, LOAD LIMIT

A number of factors determine the extent to which seawater influences the pond. Tidal flushing is defined by bathymetry and other physical characteristics within the pond itself and by the size and nature of the inlet. At some point in its early history, Lagoon Pond must have been fully open to Vineyard Haven Harbor. Most of Beach Road, Lagoon Harbor Park, and Eastville Beach are on a baymouth barrier beach that built itself across the opening, similar to the barriers that protect Sengekontacket Pond and Katama Bay. The barrier beach protecting Lagoon Pond was known in our early written history as "Canal Flats". From the earliest maps, we know that the present inlet at the drawbridge did not exist in the late 18th century. Our earliest maps, such as the DesBarres chart of 1775, show the inlet at the head-of-the-harbor side of the barrier. Ferry Boat Island acquired its name during that time period. Isaac Chase's ferry operated from the little island. Recorded history tells us that the Bass Creek inlet was partially closed by the gale of 1815 and was subsequently closed by fill in 1835. The inlet was in its present location as early as 1845, as shown on the chart. It is likely that the inlet has had a history of shifting episodically in response to storms, as is the habit of barrier beach inlets. Needless to say, the inlet position has had a dramatic effect on circulation in the West Arm. When the Bass Creek inlet was open, there was quite a tidal flow through it, as the relict channel illustrates. The tidal channel which ran the length of the West Arm shows up well on the 1847 Survey chart, and still appears on modern aerial photos and charts, although it has shoaled in considerably. Private concerns have dredged in the Mud Creek area and the Town of Tisbury also performed some dredging there. Maintenance dredging in the West Arm is needed for navigation and berthing associated with two boatyards and the Town Landing.

In the early part of this century, the Town and Commonwealth stabilized the present entrance to Lagoon Pond by construction of the Eastville jetty and by dredging the present channel. The Commonwealth also constructed and reconstructed the existing bascule drawbridge with a 30' horizontal clearance across the inlet. In 1968, the U.S. Army Corps of Engineers adopted the entrance channel for commercial navigation and dredged it to a depth of $8^{\prime}$, a width of $100^{\prime}$ and a length of 200', and extended the Eastville jetty by 200'. There has been no maintenance dredging of the channel.

A box culvert connects Mud Creek to Lagoon Pond. Because boat access is not a concern, a roadway crosses the inlet over the culvert. Another type of fixed opening is the anadromous fish run, a pond opening designed
specifically to facilitate the spawning (and capture) of herring and alewives. The importance of anadromous fish runs should not be underestimated. The herring and alewives figure prominently in the marine food chain as "bait fish" which are eaten by larger fish, some of which have significant commercial and recreational value. They need access to the freshwater ponds to spawn, in order to keep up the stock. These fish also manage pond nutrients, in a way, by consuming nutrients in the pond while growing. The runs have cultural value as well, particularly the historic runs. The towns of Oak Bluffs and Tisbury cooperated with the M.V. Shellfish Group, the Mass. Division of Marine Fisheries and the USDA Soil Conservation Service to construct a fixed run for Upper Lagoon Pond, the site of a historic run. According to the 1995 Annual Town Report of the Oak Bluffs Shellfish Department "After years of planning, construction and stocking of fish, the oak Bluffs and Tisbury Herring Advisory Boards petitioned the director of Marine Fisheries, Phil coates, for local control of the herring run at the Head of Lagoon Pond. On January 13, 1995 the Oak Bluffs Board of Selectmen received a letter from the Division of Marine Fisheries granting the Towns of Oak Bluffs and Tisbury local control of the herring fishery. Twenty-eight licenses were sold this first year and the harvest of herring has once again become an annual event in oak Bluffs." According to the 1997 Tisbury report "We had a successful herring season once again. The herring run seems to be a popular spot with the increase of herring coming into Lagoon Pond. The result has made fishing for bass \& blues very rewarding in Lagoon Pond."

## TIDAL EXCHANGE

In 1998, MVC recorded tidal data through a lunar cycle in the pond. Three Global water level recorders were placed in the pond from November 10 through December 10. The three locations selected were at the Drawbridge, at the marina in the West Arm and at the MV Shellfish Group Hatchery toward the southern end of the main body of the pond. The gauges were programmed to record the water depth over the pressure transducer at 10 minute intervals. The devices are temperature, pressure and salinity compensated. The manufacturer indicates $.2 \%$ accuracy. There was a storm on November 16, and no other unusual weather occurrences.

All three tide curves are semi-diurnal and show strong similarities of both the major and the minor features of the tidal hydrograph. The average tide range was found to be very close to 1.75 feet ( 0.53 meters) at all three stations. There is significant coincidence of the time of high and low water at all three stations, typically within 20 minutes or less. The curve is flood dominated, as indicated by the duration of each phase of the tidal cycle. Average time of the flood stage ranges from 6:39 hours at the Drawbridge to

## Tide Level at Maciel Marine, Lagoon Pond

10 November to 11 December 1998

6:51 hours at the West Arm. On average, ebb tide persists from 5:45 hours at the Shellfish Group pier to 5:37 hours at the West Arm. On average, a tidal cycle requires 12:31 hours to complete in the main body of the pond and 12:28 hours in the West Arm. There are approximately 1.93 tidal cycles per day.

In 1978, M.V.C. ${ }^{17}$ investigated tidal circulation in the pond. Nearly coincident rise and fall of the tide and approximately equal tide ranges at all three stations indicated good tidal circulation. The 1998 M.V.C. findings are consistent with the earlier assessment of good tidal circulation. Perhaps the good circulation comes from the depth and elongation of the main body of the pond. Prevailing southwest and northwest winds cut across the pond diagonally, and are tempered by the high bluffs on either side of the pond. Tidal circulation in the pond is not impacted by the prevailing winds, as might occur in a broad and shallow pond.

In his 1986 report ${ }^{18}$, Gaines found a double high tide feature, with a pattern of salinity variation that suggested to Gaines that harbor water entering the Lagoon is efficiently carried into the pond and that ebbing water is efficiently carried out of the inlet. A more gradual salinity change would have indicated sloshing of the same water back and forth. He suggested subsidence of the incoming salt water into the deeper basins, with subsequent ebb of surface water, making for a very efficient tidal exchange system. He also found high salinities near the southern end of the pond, indicating "some kind of upwelling process is active to displace the fresher water and bring more saline water to the surface at the head of the Lagoon.". He also found that freshwater input was fairly uniform in the main body of the pond, but that the West Arm showed strong freshwater influence from Mud Creek.

In the Diagnostic/Feasibility Study ${ }^{19}$, Poole stated a tidal range of .73 meters, quite different from the MVC measurement of .53 meters. Poole recorded tide levels for several tidal cycles (5/21-24/86 and 6/29-30/86), rather than throughout a lunar cycle as was done in the MVC investigation. Poole's measurements may not have been representative of the full cycle.

Further investigation of the complexities of circulation in the Lagoon may be appropriate. The pond has an unusual configuration, to say the least. The main body

[^6]of the pond is long, narrow and deep, and, in contrast, the West Arm is shallow throughout. If there was some stratification in the deeper parts of the pond, it is conceivable that there could be some impact on circulation. M.V.C. has not found any evidence of stratification, but that doesn't mean it could not occur during some wind and tide conditions. It is possible that stratification could leave some of the deeper water out of the tidal cycle, and it is possible, as some have suggested, that stratification increases flushing because the fresh water may leave first, taking most of the nutrients.

## RESIDENCE TIME

Residence time is the number of days of tidal flushing required to completely exchange old water for new, or the time it takes for newly input fresh water to arrive at the Drawbridge and exit the pond through the inlet. There are two simple ways to compute tidal flushing. The average depth at mid-tide may be divided by the tidal range. M.V.C. estimated an average depth of 2.83 meters at Mean Low Water, using a planimeter and the 1984 N.O.A.A. Chart for Martha's Vineyard - Eastern Part to create the hypsograph as shown on the following page. Using M.V.C.'s depth estimate (adding part of the tidal range, for an average depth at mid-tide of 3.095 meters) and the MVC tidal range measurement of . 53 meters results in a flushing estimate of 5.8 tidal cycles. Assuming that not all water indicated in the tide range is actually completely new water exchanged for old water, this figure can be modified to give the estimated time to exchange $95 \%$ of the old water. This is three times the calculated flushing time, or 17.52 tidal cycles. At 1.93 tidal cycles per day, this yields a residence time of 8.76 days.

Another method to calculate flushing involves dividing the Mean Low Water volume by the difference in volume between Mean High Water and Mean Low Water. According to M.V.C.'s planimeter measurements and depth calculations, the Mean Low Water Volume is 1650.43 million gallons and the tidal prism is 308.79 million gallons. Computing flushing time from those volume estimates results in an estimate of 5.34 tidal cycles, which corresponds to 8.3 days estimated to exchange $95 \%$ of the pond's water. This estimate is quite consistent with the estimate of 8.76 days, computed from the depth and tidal range. Averaging the two, M.V.C. has selected 8.53 days as the most likely estimate for residence time.

The M.V.C. estimate stands in marked contrast to some of Poole's calculations. Poole estimated a tidal exchange of 23.1 percent per tide or 46.2 percent per day. Poole considered that the exchange would be adequate, if the tidal waters were better mixed: "However, the influent saltwater

enters the estuary from underneath, and on low wind days mixing is poorly accomplished by advection or convection currents.". In order to estimate tidal flushing, Poole used a calculation known as the modified Prism Method (Ketchum, 1951), to estimate a flushing rate of 42.9 per year for the West Arm and 4.5 flushings per year for the main body of the pond ( 80.9 days for the main body of the pond and 8.5 days for the west Arm). He checked that calculation by using another method, called the Fractional Freshwater Method, which compares pond and harbor salinities. Using that method with a mean in-pond salinity of 32.9 ppt , he calculated a flushing rate of 58.9 days, or 6.2 tidal flushings per year. Why is there such a disparity between the MVC estimate and two of the Poole flushing estimates? It could be that the Modified Prism Method and the Fractional Freshwater Method are designed to calculate estuarine flushing that involves river discharge. Because there is no river discharge in Lagoon Pond, those methods may not be applicable. In its latest report on nitrogen loading ${ }^{20}$, the Buzzards Bay Project has indicated that Ketchum's flushing formula may be more appropriate for vshaped estuaries that receive most freshwater and nitrogen from riverine discharge and that the method is inappropriate for embayments that receive little fresh water or that receive most of the fresh water from groundwater.

[^7]
## NITROGEN LOADING LIMIT

MVC has used the formulas developed by the Buzzards Bay Project, as recently modified ${ }^{21}$, to determine the nitrogen loading limit for the pond. With a flushing time of 8.53 days and an average depth at mid-tide of 3.095 meters, the Lagoon falls into the deeper pond category as defined by the Buzzards Bay Project. The revised limits are used for the following calculations:
for Outstanding Resource Waters:
$50 \mathrm{mg} / \mathrm{m}^{3} / \mathrm{Vr}=17,084 \mathrm{~kg}$
for SA Waters:
$150 \mathrm{mg} / \mathrm{m}^{3} / \mathrm{Vr}(\mathrm{SA}$ waters) $=51,253 \mathrm{~kg}$
Considering that the pond exhibits some signs of stress from the existing load, as seen in decline of eelgrass beds, e.g., the more conservative approach appears to be the prudent choice. Therefore, even though Lagoon Pond is presently classified "SA", it seems more appropriate to strive for the higher quality of the outstanding Resource Waters class. The recommended limit for the watershed is 17,000 kilograms per year.

[^8]
## Loading Limit Calculations

(SA loading rate) (volume at mid-tide) $(1+$ square root of residence time)

```
residence time x 1,000,000
```

$\frac{\left(150 \mathrm{mg} / \mathrm{m}^{3}\right)\left(6,823,856 \mathrm{~m}^{3}\right)(1+\text { square root of } .023 \mathrm{yr})}{.023 \mathrm{yr} \times 1,000,000}$

$$
=\quad 51,253 \mathrm{~kg} \quad \text { SA limit }
$$

(ORW loading rate) (volume at mid-tide)(1+square root of residence time)

```
residence time x 1,000,000
```

$=\frac{\left(50 \mathrm{mg} / \mathrm{m}^{3}\right)\left(6,823,856 \mathrm{~m}^{3}\right)(1+\text { square root of } .023 \mathrm{yr})}{.023 \mathrm{yr} \times 1,000,000}$
$=\quad 17,084 \mathrm{~kg} \quad$ ORW limit

```
area of pond = 220.48 hectares
mean depth at MLW = 2.8 m
tidal prism volume = 1,168,544 m
volume at mid-tide = 6,823,856 m}\mp@subsup{\textrm{m}}{}{3
residence period = 8.53 days = .023 yr
```

COMPARISON OF LIMIT TO EXISTING AND PROJECTED LOADS
MVC has defined a load limit of 17,000 kilograms per year. MVC has previously determined that the existing load to the system is 17,240 kilograms, the load with low growth would be 20,514 kilograms, the load with moderate projected growth would be 22,285 kilograms, and the load projected for high growth would be 26,652 kilograms. None of the estimates fall under the proposed $\operatorname{limit}$ of $17,000 \mathrm{~kg}$.

## MANAGEMENT MEASURES

The first management recommendation is to adopt a nitrogen limit of 17,000 kilograms per year for the watershed.

EXISTING NITROGEN LOAD AND PROJECTIONS

|  | Kilograms/year |
| :--- | :---: |
| Current Nitrogen Load | 17,240 |
| Nitrogen Load at Low Growth | 20,668 |
| Nitrogen Load at Moderate Growth | 22,439 |
| Nitrogen Load at High Growth | 26,806 |

In order to plan for a specific total nitrogen load, it is necessary to review the distribution of the load, and to then address each individual component. The present load is calculated to be distributed as follows:

Kilograms/year

| Septic Systems |  |
| :--- | ---: |
| Residential | 7,597 |
| Commercial | 1,436 |
| Rain | 6,413 |
| Farms | 1,062 |
| Lawns | 732 |
| Total | 17,240 |

Management measures for each individual component follow:

SEPTIC SYSTEMS
The first consideration regarding septic systems is that the two towns should determine their needs and desires for growth in their towns, and more specifically, in the watershed area.

If the towns determine that new growth is appropriate or desirable for the watershed area, then it would be necessary to somehow restrict the nitrogen impact of the new development.

The towns should consider revising zoning and Board of Health regulations to support the 17,000 kilogram limit.

Exclusive of rainfall and pond acreage, the limit allows for $3.7 \mathrm{~kg} /$ acre devoted to land use impacts only. (Overall, the limit allows $3.9 \mathrm{~kg} /$ acre, including rainfall on the pond and runoff.) The towns have at their disposal a variety of means to control growth, density and the resulting increased nutrient input. The 1998 oak Bluffs Master Plan includes a recommendation to amend the zoning by-laws for the $\mathrm{R}-1, \mathrm{R}-2$ and R-3 districts to remove provision for remainder lots; instead contiguous lots could be combined to achieve the minimum lot sizes of 10,000 square feet in the R-1 District, 20,000 square feet in $R-2$ and 60,000 square feet in $R-3$. The Town followed the Planning Board's recommendation and voted the proposed regulation at the April 2000 Annual Town Meeting. There should result a savings in overall density at buildout.

The District of Critical Planning Concern designation process is quite expedient for setting up nutrient control protection, with the potential to create powerful overlay district zoning for one or more towns in a watershed. In fact, the Martha's Vineyard Commission did vote, in 1988 , to designate the Lagoon Pond District as a District of Critical Planning Concern. The District includes the waters of the pond and lands within 1500 feet of the mean high water line of the pond. The District excludes the commercial waterfront on the West Arm and the Lagoon Harbor Park. The designation included the goals "to maintain water quality, prevent pollution, promote wildlife habitat, promote the economic development of fisheries and related industries, and maintain and enhance recreational and other uses of Lagoon Pond and environs.". In the decision, the Martha's Vineyard Commission adopted guidelines for development of regulations for the district, and the towns adopted regulations, including regulations to control density and nutrient inputs. The Oak Bluffs Board of Health adopted a regulation limiting new construction in the District to one bedroom per 15,000 square feet of lot area, and requires, as part of the disposal works permit, information on landscaping and proposed fertilizer use on the property. In the Tisbury Wetlands By-Law Regulations, Section 1.06 includes Lagoon Pond DCPC regulations for fertilizer and pesticide application "The applications of organic and inorganic fertilizers and pesticides within 100 feet of a coastal bank, salt marsh or the 100 year flood zone adjacent to Lagoon Pond and Lake Tashmoo...is prohibited...". A waiver procedure is defined in the regulation. The regulation offers protection from nutrient loading by surface water runoff of landscaping fertilizers.

Several towns in the area have adopted nutrient loading by-laws which target source reduction. The Town of Falmouth adopted an overlay district zoning amendment and amendment to its Subdivision Rules and Regulations in 1982. The Falmouth nutrient control regulation requires developers
within the watersheds of the ponds to provide information regarding the proposed nutrient loading and provides that the Special Permit Granting Authority may withhold approval if the existing condition of the receiving waters is at or above critical eutrophication levels or if the nutrient contribution from the proposed development would generate additional nutrient levels that exceed the receiving waters' critical eutrophic level. Note that the Falmouth regulations specify critical nutrient levels for both drinking water and eutrophication of surface waters. Protection of both drinking water and pond water resources in the same regulation is a sensible and practical approach. The use of 5 parts per million nitrogen for the critical level for drinking water is quite prudent for planning purposes, in order to be sure to meet the federal drinking water standard of 10 parts per million. With regard to eutrophication, the 5 ppm standard may not be protective enough. The Falmouth regulations use .75 milligrams per liter total nitrogen for the saltwater critical eutrophic level and . 02 milligrams per liter total phosphorous for the freshwater critical eutrophic level. Actual critical eutrophic levels may vary from pond to pond. Wareham, Bourne and Plymouth adopted amendments to their zoning bylaws in order to protect Buttermilk Bay, a resource shared between them, by limiting the amount of nitrogen entering groundwater and surface waters within the Buttermilk Bay watershed. The three towns adopted overlay districts to their zoning by-laws.

Another way to restrict the impacts of development is to maximize acquisition or protection of much of the remaining open space in the watershed. Individual parcels are identified in the land use database.

Sewage treatment is another means of reducing the impacts of septic systems. Tisbury initially planned a system which did not propose to service any lots in the watershed. At the 2000 Annual Town Meeting, the Town voted to add to the proposed service area, including a number of commercial lots in the watershed. In the discussion on commercial loading, detail is included regarding the planning concerns about growth in that area. The proposed addition to the service area includes some of the lots of greatest planning concern, those with large structures and large vacant areas.

Should the towns choose to encourage or allow residential growth, then it may be prudent to consider more centralized service.

## RAINFALL

At first blush, it may seem that there is little potential to manage this source. However, there is something that can and should be done. There is also a good chance that increasingly restrictive air quality regulations should reduce the amount of nitrogen in the atmosphere. Rainfall quality should be monitored to assess any improvement (or degradation). There is potential to revise the limit standard as prudent.

## STORMWATER SOLUTIONS

Structural alternatives divert, contain and/or filter runoff in order to control erosion and sedimentation as well as to remove pollutants. Diversion may be as simple as construction of $a$ curb berm at the edge of the road. Containment devices include catch basins and wet and dry detention ponds, where sediments, heavy metals and debris settle out of suspension. Catch basins trap the high velocity "first flush" or first .5" or so of rainfall, which contains most of the contaminants washed from the paved surfaces. By catching the first flush and lowering its velocity, the catch basin allows the contaminants to settle out for later mechanical removal from the basin. Infiltration trenches and basins remove soluble pollutants as well as sediment, metals and debris. Catchment devices may be used in conjunction with wet or dry detention ponds or wet marshes to remove nutrients by means of uptake by plant material.

There are a number of considerations involved in selection of an appropriate structure. Considerations include targeted pollutant, size of planning area and type of watershed, among others. There are resources available to guide in selection of a structure. The Natural Resource Conservation Service (362-9332) is an excellent source for technical assistance. They are located at P.O. Box 709, Barnstable, MA 02630. They should be contacted regarding planning assistance to address the issues of fecal coliform contamination found in runoff, per the Gaines 1991 study. That study pointed out the need to address stormwater remediation particularly in the vicinity of the coves along the southwestern shore There are also a number of reference texts available for study, including: Controlling Urban Runoff: A Practical Manual for Planning and Designing Urban BMP's Thomas Schueler, Metropolitan Washington Council of Governments, 1987, and Decisionmaker's Stormwater Handbook Nancy Phillips, USEPA Region 5, 1992.

Runoff enters Lagoon Pond in a number of locations; notably Lagoon Avenue, Hudson Avenue and Vineyard Avenue Extension in Oak Bluffs, and Mud Creek in Tisbury. Tisbury has begun to explore innovative technologies to treat
stormwater runoff. The Town installed a limestone catch basin at Mud Creek. The limestone is intended to neutralize the acidity of the stormwater, thus helping to settle out pollutants. The Tisbury Board of Health and Department of Public Works have worked cooperatively with the pond advocacy group Tisbury Waterways, Inc., on the project. The latest phase has installed 28 limestone catch basins in the vicinity of Lake Tashmoo. The Town is planning extensive upgrade to the stormwater collection system in the vicinity of Mud Creek.

The Oak Bluffs Board of Health has adopted Stormwater Management Regulations ${ }^{22}$ which are intended to "properly manage stormwater by providing adequate protection against pollutants, flooding, siltation, and other drainage problems". The regulations apply to all new construction and alteration in Sensitive Resource Areas, and provide for development of a stormwater management design and plan so that the drainage for the subdivision or project shall not cause an increase or decrease in the volume of runoff discharged off site, for storms of $1,10,50$ and 100 year frequency.

## AGRICULTURE

Because there is much local appreciation and desire to promote agriculture, it would be difficult to restrict agricultural use. In order to protect water quality in the pond, it might be more prudent to focus water quality planning on protection of the immediate shoreline from direct contamination, rather than on the overall nitrogen load.

It may be possible in some circumstances, such as agriculture as an adjunct of open space ventures, to promote low-nitrogen farm activities where practical. Hay and legumes are examples of such crops.

## SHELLFISH AND HERRING

Promote shellfish as nutrient consumers, along with herring. Ensure that their habitats are protected. As filter feeders, shellfish "clean" the water of small particulate nutrients. Young herring also consume particulate organic nutrients as they grow, and eventually leave the pond attractively packaged for consumption by bigger fish or by humans.

Educate homeowners and professional landscapers about using native plants and about fertilizer impacts. The towns could consider limiting lawn size in the watershed, through DCPC regulations. Application of fertilizers is a practice which is much more difficult to regulate. Education is probably the more effective tool to persuade homeowners to follow label instructions regarding application, to use fertilizers with slow-release nitrogen, or to abstain altogether. Landscaping with native plants is an attractive and low-maintenance alternative to suburban turf. Local nurseries carry native plants in stock. The following reference material, listing species by height for view planning, was prepared by William Wilcox of the University of Massachusetts Cooperative Extension:

## NATIVE PLANT SPECIES

## FURTHER ASSESSMENT AND MONITORING

There is a need to continue to monitor eelgrass and algae populations. Further investigation of the complexities of circulation in this unusually long, narrow and deep water body may be appropriate. Continued surface water sampling is also in order.

1. ADOPT 17,000 KILOGRAMS AS AN ANNUAL LOAD LIMIT FOR THE HATERSHED.

## SEPTIC SYSTEMS

- Determine growth needs and desires for the watershed area in both towns.
- Encourage advanced nitrogen removal for new septic systems and consider possible extension of Tisbury municipal sewer service area.
- Revise zoning and board of health regulations to support the $17,000 \mathrm{~kg}$ limit. Consider a watershed-wide DCPC to develop and implement those regulations.
- Maximize acquisition or protection of much of the remaining open space in the watershed. Particularly consider the 370.38 acres with further subdivision potential.

## RAINFALL AND RUNOFF

- Construct and maintain structural solutions where needed to remediate existing problems, particularly in the vicinity of Mud Creek in Tisbury and the specific sites at Hudson Ave., Lagoon Road and Vineyard Ave. Extension in Oak Bluffs. Review town regulations regarding proper drainage design in future projects; Tisbury might want to adopt stormwater regulations similar to those adopted by the Oak Bluffs Board of Health.

## LAWNS AND LANDSCAPING

- Educate homeowners and professional landscapers about using native plants and about fertilizer impacts.

## AGRICULTURE

- Encourage low-nitrogen farm activities where practical, such as in conjunction with open space ventures. Examples are legumes such as clover, alfalfa and beans, and grass seed mixture for hay and pasture.

SHELLFISH AND HERRING

- Promote shellfish as nutrient consumers, along with herring. Ensure that their habitats are protected.

## 2. FURTHER ASSESSMENT AND MONITORING

- Continue water sampling, particularly focusing on the "tributaries". Include some continuous recorded logs of dissolved oxygen over several daily cycles together.
- Perform updates to the eelgrass inventory, at five year intervals. Watch for changes in the algae and weed population.
- Continue to investigate the complexities of circulation in the pond. Ensure that the flushing formulas used to calculate the nitrogen loading limit are appropriate for the realities of circulation in this unusually long, narrow and deep water body. Investigate stratification in the deeper areas.

## APPENDIX I

## SELECTED HISTORICAL AND NAME REFERENCES FROM BANKS' <br> THE HISTORY OF MARTHA'S VINEYARD DUKES COUNTY

 MASSACHUSETTS ${ }^{23}$"It is probable that smaller communities made abiding-places within the limits of the territorial authority of each petty sachem. In this way, I believe, we may infer that Wekwetuckauke (the lagoon), Sanchacantacket, Onkokemmaug (North Tisbury) and Nashowakemmuck (Chilmark) were the locations of such subordinate villages. Of the character of these settlements it can be said that they had no permanency. Composed as they were of loosely constructed wigwams, they were easily transported from place to place, as the requirements of the season demanded. In the summer they were doubtless picketed about the inlets of the coast, while in winter they were removed to the protection of the woods and hills from the icy blasts of the north. The circumscribed territory, however, prevented extended migration, and within a small compass the various companies owning fealty to the local great men, moved from place to place, when the refuse heaps became too large or the game grew too wary. Their dwellings were known as wigwams, a corruption of the Algonquian word 'wekowomut', meaning in our language, a house. The younger Mayhew described these structures as 'made with small poles like an arbor covered with mats, and their fire is in the midst, over which they leave a place for the smoak to go out at'. This was in 1650, and probably is a correct description of them as they were used before the coming of the whites. The island Indians did not use skins for a covering like those on the mainland, as there were not any animals numerous enough to supply them for that purpose. The mats were woven from the common marsh flag, or flower-de-luce, and probably long, native grasses were added for binding."
"Weaguatickquayage (l673). This name, denoting the land at the head of Lagoon pond, is spelled in a variety ; of ways, owing to its complicated formation. The more modern form is an abbreviated one, Weahtaqua, and it is sometimes spelled Webbataqua, which is fanciful as well as incorrect. It occurs frequently through New England, and an early instance of it is on the neighboring island of Nantucket. It is a compound of We-a-qua-tukq-auke, which is a word meaning 'land at the head of the tidal cove.' In the court records of 1685 the bounds of 'homses hole neck' were adjudged by Samuel Tilton and Thomas Mayhew as arbitrators ' to have bin set by towonticut by a fut path which gose from wakuttockquayah unto cuttashimmoo on the other side of the neck.' Matthew Mayhew wrote it Waquittuckquoiake (Deeds, I, 69). 'at holms his hole or the Springs at the head of that Cove called Wehtaqua' (Mass. Arch., CXII, 422; dated June, 1692) shows the gradual elision."

[^9]"Bass Creek. A Salt-water creek which emptied the Lagoon. Its original course may have been midway of the beach which separates the harbor, but before 1781 it had cut a channel along the line of Water Street, and was six or seven feet deep a century ago. Small draft vessels entered this creek and discharged cargoes on the shore adjoining the "Great House' and other inns in that vicinity. It derived its name, probably, from an incident occurring in the winter of 1778 following Grey's Raid, when a large number of bass were frozen in the creek and furnished food to the impoverished inhabitants."
"Ferry Boat Island. The larger of two grassy islands in front of the Marine Hospital is called Ferry Boat, because it was the landing site of Isaac Chase's ferry in colonial days."
"Lagoon. This body of salt water was originally called the harbor of Homes Hole, and later, until about 1740, Waketaquay pond or some form of that Algonquian place name. It is first of record as the lagoon of salt water' about 1743 , as far as known, being then so called in a deed. From that time forward, this name was applied to it with increasing frequency, until it had supplanted all other names. It is an English derivative from the Spanish and Italian words laguna (Latin lacuna), meaning a lake in general terms. In the restricted sense it is applied to a lake or body of water on a coast, formed by a belt or reef of sand thrown up by sea action. This is the actual topography of our Lagoon, but by whom it was so called at first is not known. The work may have been applied by a Spanish or Italian sailor who happened in the harbor, or by a resident who had sailed the Spanish Main and learned the significance of the word."
"Quinnaamuk. This name occurs in an Indian deed dated March 14, 1669, and appears later also as Quinniummuh. (It designated a beach 'commonly called the long beach' and may refer to the long strip of sandy beach separating the Lagoon and harbor at that time. Deeds, II, 51; VI, 4l2.) Quinniaamuk was one of the Indian fishing stations. The meaning of the work is 'place where the long fish (lamprey eel) is taken. At certain seasons of the year, when an inlet is cut through some of these beaches, there is a rush of these eels for the salt water."
"Tikhomah. This was the name of a place near the head of the Lagoon, and is referred to in a deed, or Indian writing, conveying certain property at Weaquitaquayage (Deeds, IV, 348)."

## APPENDIX II

## PUBLIC SEB8IONS, COMMENTS AND REBPONBES

## JULY 11, 1999 PREBENTATION TO THE LAGOON POND ABSOCIATION

In July, 1999, MVC and the Islands Watershed Team presented material on water quality in Lagoon Pond at the annual meeting of the Lagoon Pond Association, at Sailing Camp Park in Oak Bluffs. The presentations focused on health of the eelgrass beds and on overall circulation in the pond, including results from MVC's tidal investigations. A large crowd was present. Participants expressed their concern for perceived deterioration in the water quality in the pond, particularly the deterioration of the eelgrass beds.

LAGOON POND
AUGUST 3, 2000, 4:00 P.M. SAILING CAMP PARK, OAR BLUFFS

The meeting was opened by Jo-Ann Taylor at 4:10 P.M.
In attendance were:
Rick Karney M.V. Shellfish Group
Don Hill Lagoon Pond Association
Derek Cimeno Tisbury Shellfish
Dave Grunden Oak Bluffs Shellfish
Liz Durkee Oak Bluffs Conservation Commission

Participants generally agreed with using a very conservative limit for the Lagoon. They prefer the "ORW" limit of 17,000 kg to the "SA" limit of $51,000 \mathrm{~kg}$. They all suggested that there is much evidence in the pond that the existing load seems to be more than the pond can take, considering the current problems with growth of algae.
D.G. reported evidence of a dinoflagellate Prorocentrum, that is known to be hazardous to shellfish, and suggested circulation studies such as W.H.O.I. did in Sengekontacket. He also noted that the flat just outside of the pond is growing rapidly. R.K. added that they have had repeated problems at the shellfish hatchery with dinoflagellate blooms, particularly around Labor Day; they have had blooms of dinoflagellates that live mostly on bacteria; and that
they have found 5-10\% undesirable algae species at the lobster hatchery (closer to the drawbridge) and 90\% at the shellfish hatchery (closer to Upper Lagoon Pond). He suggested reviewing the recent Howes calculations that suggested a critical status for the pond. He attributes that to different circulation, and suggested further circulation studies, such as a Drogue study. D.H. noted that the lobster hatchery area is in full sunlight all day, while the shellfish hatchery area (at the bottom of a bluff) is shaded for much of the day. J.T. expressed confidence with the M.V.C. circulation assessment, based on tide gauge and hypsograph data, but proposed that there may be something about the unique geometry of the pond that keeps it from fitting into the Buzzards Bay formula well. That's why the recommended limit is the more conservative "ORW" standard.

LAGOON POND
AUGUST 31, 2000, 4:00 P.M. SAILING CAMP PARK, OAR BLUFFS

The August 3 session was repeated on August 31, for anyone who was unable to make the August 3 session. The presentation, attendance and comments were similar to the August 3 session.

## COMMENTS

Drafts of the report were circulated to DEP and to town boards and other agencies. Written comments were received from Pamela Truesdale, DEP, and David Grunden, Oak Bluffs Shellfish Constable. Oral comments were received from Gary Gonyea, DEP, and William Wilcox, MVC. Those comments were appreciated and considered in editing the draft to produce this final report. The comment letters are included here.

MEMO
TO: JoAn Taylor, MVC
FROM: Pamela Truesdale, DEP
RE: Draft Final reports for Lagoon and Tisbury Great Ponds
$\mathrm{Hi}, \mathrm{Jo}-\mathrm{Ann}$. I have read through both of the draft final reports, and overall, both look excellent.
I have only one real comment. This relates to both reports. The only aspect I puzzled over was the growth projections for builclout and nitrogen impacts, ie. the "low growth", "moderate growth" and "high growth" figures. I think it would be helpful if a better explanation of what these growth numbers mean was incorporated into the text. For example, can you place growth percentage numbers on each of the growth categories .. like "low" growth is a $2 \%$ increase over current figures (as an example). That would help me (and hopefully anyone else reading the Final Reports) better understand the ramifications of the anticipated nitrogen loadings associated with these growth scenarios.

I thought the reports were detailed and thorough, and although I am familiar with the project, learned quite a lot more in reading them!

Finally, have all of the final public meetings been held on the Vineyard ? If not, I would be most interested in attending one or more of the meetings, in particular to hear what the public comments are, if this is still a possibility. Let me know.

Call me if you have any questions. (508) 946-2881.
Thanks for your excellent work on this grant.

## Jo-Ann Taylor

MV Commission

## Hi Jo-Ann,

In reviewing the draft "Nutrient Loading to Lagoon Pond", I wanted to bring up a couple of things. I think it would strengthen the case to use the orw standard if you were more specific about some of the observable indicators of already elevated nitrogen in the pond. The two that come to mind are the increased growth and abundance of the green macroalgae Enteromorpha and the presence of the fungus root rot on the eel grass (Zostera marina). It is has been stated, by Phil Collaruso (I think) that this fungus is only successful against the eel grass because the eel grass plant is already stressed from elevated nitrogen.

The other change I would like to see is the inclusion of both Maderias Cove and Vineyard Ave. Ext. as notable areas that storm water runoff enters the Lagoon (page 37). This would probably help as this report could then be cited in applying for the Coastal Pollution Remediation funding that we discussed the other day.

One other small thing is you should spell out all your anachronisms at least once in the report. Ie: do you mean Best Management Practices by BMP?

Thank you for the opportunity to comment,

Dave
